

Android App Development – Calculator with static layouts and view and data binding – Practical task

- As for practicing please create the new project called ICalculatorWithStaticLayouts
- Pls use the layout we worked out on one of our previous labs

- And implement the functionality of a “classical” calculator with all the basic operations
- Application needs to be based on static layouts and view- and databinding mechanisms that we are practicing
- The application should be (reasonably 😊) resilient to erroneous input like no data provided, division by zero etc.
- When done, please upload to the UPEL short video cast presenting the code and how your app is working, and pls share the code on the gitlab as well Thank you.
